Introduction

What we've seen so far

- Nonparametric regression using smoothers
- ► Different types of smoothers: e.g. kernel and local polynomial

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Penalized regression

Today

- Construct basis functions that are
 - Multiscale
 - Adaptive
- Find sparse set of coefficients for a given basis

Introduction

- In nonparametric regression we estimated the unkonwn function f directly
- ▶ With wavelets we use a orthogonal series representation of *f*
- This shifts the estimation problem
 - from directly estimating f
 - \blacktriangleright to estimating a set of scalar coefficients that represents f
- Similar to penalized regression but regularization will be replaced by thresholding
- Wavelets are used in the image file format JPEG 2000 to compress data

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Assumptions

Obervations

$$Y_i = f(x_i) + \epsilon_i$$
 $i = 1, \ldots, n$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

- The ϵ_i are iid
- The function f is square integrable $\int f^2 < \infty$
- ▶ Defined on a close interval [*a*, *b*]

Basis Function

- A set of functions Ψ = {ψ₁, ψ₂, ...} is called a basis for a class of functions F
- If any function f ∈ F can be represented as a linear combination of the basis functions ψ_i
- Written as

$$f(x) = \sum_{i=1}^{\infty} \theta_i \psi_i(x)$$

with θ_i are scalar constants refered to as coefficients

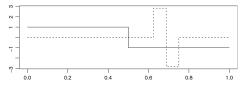

The constants θ_i are inner products of the function f and the basis functions ψ_i

$$\theta_i = \langle f, \psi_i \rangle = \int f(x) \psi_i(x) \, dx$$

- The basis is orthogonal if $\langle \psi_i, \psi_j \rangle = 0$ for $i \neq j$
- The basis is orthonormal if orthogonal and $\langle \psi_i, \psi_j
 angle = 1$

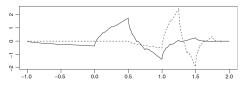

Basis Function

- Many sets of basis functions
- We consider orthonomal wavelet bases
- A simple wavelet function was first introduced by Haar in 1910

Source: Hollander, Wolfe, and Chicken (2013)

 More flexible and powerful wavelets were developed by Daubechies in 1992 and many others

Source: Hollander, Wolfe, and Chicken (2013)

э

 \blacktriangleright We consider wavelet functions ψ

$$\Psi = \{\psi_{jk} : j, k \text{ integers}\}$$

with

$$\psi_{jk} = 2^{j/2} \psi(2^j x - k)$$

that form a basis for square-integrable functions

- \blacktriangleright Ψ is a collection of translations and dilations of ψ
- The ψ is constructed to ensure the the set Ψ is orthonormal
- The property ∫ ψ_i² = 1 implies that the value of ψ is near 0 except over a small range
- ► This property combined with the constrution above means that as j increases ψ_{jk} becomes increasingly localized

- \blacktriangleright A careful construction of ψ leads to a multiresolution analysis
- It provides an interpretation of the wavelet representation f in terms of location and scale by rewritting

$$f(x) = \sum_{i=1}^{\infty} \theta_i \psi_i(x)$$

in terms of translation k and scaling j as (\mathbb{Z} is set of integers)

$$f(x) = \sum_{j \in \mathbb{Z}} \sum_{k \in \mathbb{Z}} \theta_{jk} \psi_{jk}(x)$$

- This can be intepreted as approximation at different scale j
- Here scale j is the same as frequency
- For a fixed j the index k represents behavior of f at resolution j and a particular location

Consider the approximation

$$f_J(x) = \sum_{j < J} \sum_{k \in \mathbb{Z}} heta_{jk} \psi_{jk}(x)$$

- As J increases f_J is able to model smaller scales (higher frequncy) behavior of f
- Corresponds to changes that occur over smaller interval of the x-axis
- As J deceases f_J models larger scale (lower frequency) behavior of f
- Adding gloabl scaling term (think of it as the intercept)

$$f_J(x) = \sum_{k \in \mathbb{Z}} \xi_{j_0 k} \phi_{j_0 k}(x) + \sum_{j_0 < j < J} \sum_{k \in \mathbb{Z}} \theta_{j k} \psi_{j k}(x)$$

Consider a simple example

$$f(x) = x, \quad x \in [0,1)$$

The Haar wavelet functions are defined as

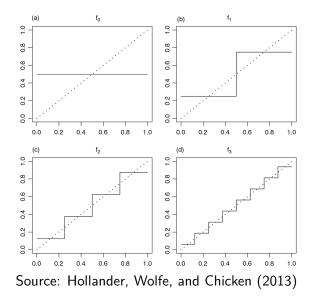

$$\psi(x) = \begin{cases} 1, & x \in [0, 1/2), \\ -1, & x \in [1/2, 1) \end{cases}$$

and

$$\phi(x) = 1, \quad x \in [0,1)$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三回 のへの

Discrete Wavelet Transform

- The simple linear function example has exact solution to determine coefficients
- Usually this is not the case and numerical approximations are necessary to estimate coefficients
- One numerical methods is called the cascade algorithm by Mallat 1989
- It works if the sample size is a power of 2

$$n = 2^J$$

for some positive integer \boldsymbol{J}

• Using this algorithm restricts the upper level of summation to J-1 with

$$J = \log_2(n)$$

Sparsity

- Wavelet methods are closely related to the concept of sparity
- A function

$$f(x) = \sum_{j} heta_{j} \psi_{j}(x)$$

is sparse in a basis ψ_1, ψ_2, \ldots if most of the θ_j are zero (or close it zero)

Sparsity is not captured well by the L₂ norm but it is capture by the L₁ norm

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬぐ

Sparsity

► For example,

$$a = (1, 0, ..., 0)$$
 $b = (1/\sqrt{n}, ..., 1/\sqrt{n})$

• then both have the same L_2 norm

$$\|a\|_2 = \sqrt{1+0+\dots+0} = 1$$

 $\|b\|_2 = \sqrt{1/n+\dots+1/n} = \sqrt{n \times 1/n} = 1$

but with L₁ norm

$$\|a\|_1 = 1 + 0 + \dots + 0 = 1$$

 $\|b\|_1 = 1/\sqrt{n} + \dots + 1/\sqrt{n} = n \times 1/\sqrt{n} = \sqrt{n}$

- Monthly sunspot numbers from 1749 to 1983
- Collected at Swiss Federal Observatory, Zurich until 1960, then Tokyo Astronomical Observatory
- Sunspots are temporary phenomena on the photosphere of the sun that appear visibly as dark spots compared to surrounding regions
- They correspond to concentrations of magnetic field flux that inhibit convection and result in reduced surface temperature compared to the surrounding photosphere

Monthly sunspot numbers 150

50

0

- The original data has length 2820, but only the first 2048 are used here to make it a dyadic number
- So the modified data is now from January 1749 to July 1919

50% Thresholding

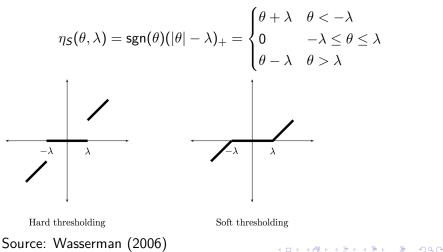

▲ロ▶ ▲圖▶ ▲ 国▶ ▲ 国▶ ― 国 … のへで

- The drawback of manual thresholding is the subjective choice of the threshold
- One might mistakenly chose to threshold all but few coefficients and oversmooth f
- Other methods are based on theoretical or data-driven considerations
- Many such methods are based on the assumption that the erros are normally distributed
- For instance: Donoho and Johnstone (1994). Ideal spatial adaptation via wavelet shrinkage

• Hard thresholding (wavelet coefficient θ , threshold λ)

$$\eta_{H}(\theta,\lambda) = \theta \cdot I(|\theta| > \lambda)$$

Soft thresholding

 The discrete wavelet transform operation may be represented in matrix form

$$ilde{ heta} = W \! y = W \! f + W \! \epsilon$$

Writing the unobserved coefficients as θ = Wf and the error coefficients as ϵ̃ = Wϵ, we have

$$\tilde{\theta} = \theta + \tilde{\epsilon}$$

- ► The matrix W is orthogonal by design, so the extit{\vec{\epsilon}} are still normally distributed (under the normal error assumption)
- \blacktriangleright Unless the noise is excessive, the $\tilde{\epsilon}$ are generally smaller in magnitude than θ
- Which means that under the sparsity property, error coefficients may be ignored

Donoho and Johnstone make use of this and define soft thresholding rule to θ̃ using the threshold

$$\lambda_{v} = \sqrt{2\sigma^{2}\log(n)}$$

with σ^2 being the variance of the errors ϵ

- The variance is usually not known and needs to be estimated
- ▶ They propose the "VisuShrink" algorithm using thresholding η_S

$$\widehat{\theta} = \eta_{\mathcal{S}}(\widetilde{\theta}, \lambda_{\nu})$$

• and the inverse discrete wavelet tranform W^{-1}

$$\widehat{f}_{v} = W^{-1}\widehat{\theta}$$

In general, thresholding procedure:

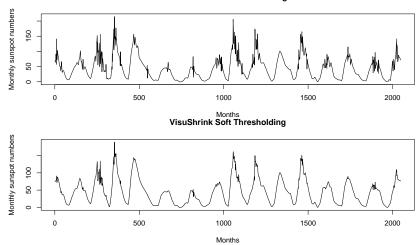

- decompose the data via discrete wavelet transform
- apply some method of thresholding
- reconstruct using the inverse wavelet tranform on the thresholded coefficients

$$\widehat{f} = W^{-1}\eta(Wy,\lambda)$$

The threshold rule can be hard or soft threshold without affecting the asymptotic mean squared error

$$\mathsf{E}\left(\frac{1}{n}\sum_{i=1}^{n}((f(x_i)-\widehat{f}_{v}(x_i))^2\right)$$

VisuShrink Hard Thresholding

▲□▶ ▲□▶ ▲臣▶ ★臣▶ = 臣 = のへで

Other Important Topics

- Different thresholding per level (Donhoho and Johnstone 1995) called "SureShrink"
- Thresholding without strong distributional assumptions on the errors using cross-validation (Nason 1996)
- Practical, simultaneous confidence bands for wavelet estimators are not available (Wasserman 2006)
- Standard wavelet basis functions are not invariant to translation and rotations
- Recent work by Mallat (2012) and Bruna & Mallat (2013) extend wavelets to handle these kind of invariances
- This provides a promising new direction for the theory of convolutional neural network
